## Overview

---

Can transient phase shift control suppress DC-bias current in dual-active-bridge converters?

By regulating the inductor current slope during the transient, this article proposes a novel transient phase shift control (TPSC) to suppress the dc-bias current in dual-active-bridge (DAB) converters, which is universal for different phase shift control strategies. First, the dc-bias current models under different transient scenarios are built.

What is a transient suppressor?

There are two major categories of transient suppressors: a) those that attenuate transients, thus preventing their propagation into the sensitive circuit; and b) those that divert transients away from sensitive loads and so limit the residual voltages.

Why are transient surges more threatening to electrical loads?

These transient surges are more threatening to electrical loads because they are not diminished over shorter distances, unlike lightning-induced impulses. In fact, lower level surges (below 6000V) actually force more current into a system because the transients pass under the radar of the air gap.

When should a suppressor respond to a transient surge?

The suppressor must immediately respond to transients before they reach their uppermost voltage values. Suppressor performance should not deviate or degrade with use when called upon to divert extreme levels of transient current. Transient surges are differentiated by their duration, frequency and amplitude.

What factors should be considered when evaluating a transient suppressor?

As a rule the source impedance of the signal and the frequency as well as the capacitance of the transient suppressor should be considered. The current

through CP is a function of  $dv/dt$  and the distortion is a function of the signal's source impedance. Each case must be evaluated individually to determine the maximum allowable capacitance.

What is a selenium transient suppressor?

Selenium Cells - Selenium transient suppressors apply the technology of selenium rectifiers in conjunction with a special process allowing reverse breakdown current at high-energy levels without damage to the polycrystalline structure.
