

Drawbacks of interconnected power system

Overview

Why do power systems need interconnections?

The interconnections, which are previously used to maintain the system's reliability, began to be regarded as a flexibility source. The use of these connections helps growing the balancing areas, and the unique flexibility mechanisms of each power system become available to neighboring systems.

Why do we need interconnectors?

Interconnectors allow each EU member to have access to a broad range of electricity generation sources (i.e., wind, solar, and hydroelectric power) from other EU members. This will increase the reliability of power supply and decrease the need for fossil fuelled power plants . .

What are the benefits of transmission interconnection?

The concept builds on the proven benefits of transmission interconnection in mitigating the variability of renewable electricity sources such as wind and solar by import and export of electricity between neighbouring regions, as well as on other known benefits of power system integration.

Can interconnecting power systems contribute to a low-carbon future?

Decarbonizing the power sector is a necessary step towards a low-carbon future. Interconnecting power systems on different continents could be a method to contribute to such a future, by utilizing highly efficient renewable resources around the globe, while simultaneously providing additional benefits of power system integration.

What challenges a power system in the present and future?

All previous tips and the details will be mentioned later, such as renewables, extensive load changes, load forecasting, resiliency, energy transactions, and uncertainties, may challenge a power system in the present and future .

Is flexibility common in the interconnected power system?

The flexibility introduced in this study is common in the interconnected power system. With the fast development of technologies in power systems, many devices will be located in power systems.
