

Internal fault of photovoltaic inverter

Overview

What are internal and external PV faults?

The internal PV faults take place inside a PV module (underneath the protective glass), on the level of PV cells, and strings. External faults localize outside the PV module protective glass and are perceived as either temporary mismatch or permanent mismatch faults.

Can a PV inverter cause a fault?

The fault current injected by the PV inverter can reach significantly lower values than synchronous distributed generator (SDG) (Nimpitiwan et al. 2007). Despite its low fault contribution, the high PV penetration can also cause malfunction of network protection devices (Bracale et al. 2017).

Does a single phase PV inverter have a fault condition?

In addition to the three-phase PV inverter, in Gonzalez et al. (2018), a single-phase PV inverter (3.2 kVA) is investigated under fault condition when operating with grid-connected functionality. During a fault, the voltage at the PCC of the single-phase PV inverter also reaches 0.05 pu, and the test results are summarized in Table 7.

What happens if a fault occurs in a solar PV system?

Reduced real time power generation and reduced life span of the solar PV system are the results if the fault in solar PV system is found undetected. Therefore, it is mandatory to identify and locate the type of fault occurring in a solar PV system.

What causes internal PV faults?

Internal PV faults take place inside the PV module itself. Their initial cause is the manufacturer's defects, poor quality of fabrication, damages due to inconvenient packaging, and improper methods of wiring.

Do grid-connected PV inverters have a fault condition?

In addition, the experimental results available in the literature are specific to the PV application. Many works in the literature address the behavior of grid-connected PV inverters under a fault condition. Some of them, specifically, investigate the fault current contribution from this equipment by means of simulations.
