

Microgrid trigeneration

Overview

What is a self-contained microgrid?

The model bases the development around a self-contained microgrid using trigeneration of power where, at the first stage, fossil fuel-powered turbines produce electricity and heat which, at the second stage, powers a steam turbine to produce more electricity.

What happens when a microgrid is present?

When the microgrid is present, heat and hot water needs are met first by trigeneration waste heat, and any unmet needs are met by the same natural gas feed that would fuel the gas turbines. Finally, Table 16 compares the calculated greenhouse gas emissions between the two scenarios with data from Tables 8, 13, 14 and 15. Table 12.

What is a Trigeneration System?

In essence, it is an integration of a thermally driven refrigeration system with CHP or cogeneration systems, which culminate to the ability of providing power basically due to electrical, cooling and heating for trigeneration systems directed by Spelling .

What is a residential microgrid?

One appealing residential microgrid application combines market-available grid-connected rooftop PV systems, electrical vehicle (EV) slow/medium chargers, and home or neighborhood energy storage system (ESS). During the day, the local ESS will be charged by the PV and during the night it will be discharged to the EV.

What is the difference between cogeneration and trigeneration?

Introduction Cogeneration also called combined heat and power (CHP) systems simultaneously produce power and useful heat. Trigeneration goes a step ahead and the waste heat generated by the energy system is further

utilized to produce cooling, so this system is also called as combined cooling, heating and power (CCHP) system.

How much natural gas does a microgrid use?

As seen in Table 15, a development incorporating a microgrid uses over 10 times the natural gas in all cases than the identical development drawing power from the local distribution grid.
