## Overview

---

The Sun is the star at the center of the Solar System. It is a massive, nearly perfect sphere of hot plasma, heated to incandescence by nuclear fusion reactions in its core, radiating the energy from its surface mainly as visible light and infrared radiation with 10% at ultraviolet energies. It is by far the most important source of.

The English word sun developed from sunne. Cognates appear in other , including sinne, .

The Sun consists mainly of the elements and . At this time in the Sun's life, they account for 74.9% and 23.8%, respectively, of the mass of the Sun in the photosphere. All heavier elements, called in astronomy, account for less than 2%.

The Sun has a that varies across its surface. Its polar field is 1–2 (0.0001–0.0002 ), whereas the field is typically 3,000 gauss (0.3 T) in features on the Sun called and 10–100 gauss (0.001–0.01 T) in .

Solar SystemThe Sun has eight known planets orbiting it. This includes four ( , , , and ), two ( and ), and two ( and ). The Solar System also has.

The Sun is a that makes up about 99.86% of the mass of the Solar System. It has an of +4.83, estimated to be brighter than about 85% of the stars in the , most of which are . It is more massive than.

CoreThe core of the Sun extends from the center to about 20–25% of the solar radius. It has a density of up to 150 g/cm (about 150 times the density of water) and a temperature of close to 15.7 million (K). By.

The Sun today is roughly halfway through the main-sequence portion of its life. It has not changed dramatically in over four billion years and will remain fairly stable for about five billion more. However, after hydrogen fusion in its core has stopped, the Sun will undergo.

The Sun is the Solar System's star and by far its most massive component. Its large mass (332,900 ), which comprises 99.86% of all the mass in the Solar System, produces temperatures and densities in its high enough to sustain nuclear fusion of hydrogen into helium. This releases an enormous amount of , mostly into as peaking in .

Why is the Sun a star?

The Sun is the star at the heart of our solar system. Its gravity holds the solar system together, keeping everything — from the biggest planets to the smallest bits of debris — in its orbit. The Sun's gravity holds the solar system together, keeping everything – from the biggest planets to the smallest particles of debris – in its orbit.

What type of energy does the Sun give off?

The Sun, also known as Sol, is a star at the center of the solar system. It is a white star that gives off different types of energy such as infrared energy (heat), ultraviolet light, radio waves and light. It also gives off a stream of particles, which reaches Earth as " solar wind ". The source of all this energy is nuclear fusion.

Is the Sun a dynamic star?

From our vantage point on Earth, the Sun may appear like an unchanging source of light and heat in the sky. But the Sun is a dynamic star, constantly changing and sending energy out into space. The science of studying the Sun and its influence throughout the solar system is called heliophysics. The Sun is the largest object in our solar system.

Are there any science fiction movies based on the Sun?

There are several science fiction films featuring the Sun in the storyline. The Heliophysics Big Year is a global celebration of the Sun's influence on Earth and the entire solar system. NASA's Solar Dynamics Observatory captured this image of an X4.5 solar flare – as seen in the bright flash in the upper right – on May 6, 2024.

What type of star is the Sun?

The Sun is a G-type main-sequence star (G2V), informally called a yellow dwarf, though its light is actually white. It formed approximately 4.6 billion [ a ] years ago from the gravitational collapse of matter within a region of a large molecular cloud.

What is the composition of the Sun?

The Sun is composed of roughly 98% hydrogen and helium, [ 41 ] as are Jupiter and Saturn. [ 42 ] [ 43 ] A composition gradient exists in the Solar

System, created by heat and light pressure from the early Sun; those objects closer to the Sun, which are more affected by heat and light pressure, are composed of elements with high melting points.

The Sun is the Solar System's star and by far its most massive component. Its large mass (332,900 Earth masses), which comprises 99.86% of all the mass in the Solar System, produces temperatures and densities in its core high enough to sustain nuclear fusion of hydrogen into helium. This releases an enormous amount of energy, mostly radiated into space as electromagnetic radiation peaking in visible light.

### Solar mass

The mass of the Sun cannot be measured directly, and is instead calculated from other measurable factors, using the equation for the orbital period of a small body orbiting a central mass. [10] Based on the length of the year, the distance from Earth to the Sun (an astronomical unit or AU), and the gravitational constant (G), the mass of the Sun is given by solving Kepler's ...
