## Overview

What are the operational principles of thermal energy storage systems?

The operational principles of thermal energy storage systems are identical as other forms of energy storage methods, as mentioned earlier. A typical thermal energy storage system consists of three sequential processes: charging, storing, and discharging periods.

How is thermal energy stored?

Thermal energy can generally be stored in two ways: sensible heat storage and latent heat storage. It is also possible to store thermal energy in a combination of sensible and latent, which is called hybrid thermal energy storage. Figure 2.8 shows the branch of thermal energy storage methods.

What are the characteristics of thermal energy storage systems?

A characteristic of thermal energy storage systems is that they are diversified with respect to temperature, power level, and heat transfer fluids, and that each application is characterized by its specific operation parameters. This requires the understanding of a broad portfolio of storage designs, media, and methods.

How energy is stored in sensible thermal energy storage systems?

Energy is stored in sensible thermal energy storage systems by altering the temperature of a storage medium, such as water, air, oil, rock beds, bricks, concrete, sand, or soil. Storage media can be made of one or more materials. It depends on the final and initial temperature difference, mass and specific heat of the storage medium.

How is thermal energy storage performed based on heat changes?

As thermal energy storage is performed based on the heat changes in an energy storage medium, first, we need to define the branch of heat. There are two types of heat change in a material: sensible and latent heat. When energy

is released from a material, the temperature of that material decreases.

How to calculate thermal energy storage materials for latent heat storage?

However, the enormous change in the volume of the storage materials is a problem and hence is not used in general. The thermal energy stored by latent heat can be expressed as (2)  $Q = m \cdot L$  where  $m$  is the mass (kg),  $L$  is the specific latent heat ( $\text{kJ} \cdot \text{kg}^{-1}$ ). 2.2.1.
